Abstract. Probabilistic Logic Programming is a promising formalism for dealing with uncertainty. Learning probabilistic logic programs has been receiving an increasing attention in Inductive Logic Programming: for instance, the system SLIPCOVER learns high quality theories in a variety of domains. However, SLIPCOVER is computationally expensive, with a running time of the order of hours. In order to apply SLIPCOVER to Big Data, we present SEMPRES, for “Structure Learning by MaPREduce”, that scales SLIPCOVER by following a MapReduce strategy, directly implemented with the Message Passing Interface.

1 Introduction

Probabilistic Logic Programming (PLP) is an interesting language for Inductive Logic Programming (ILP), because it allows algorithms to better deal with uncertain information. The distribution semantics [5] is an approach to PLP that is particularly attractive for its intuitiveness and for the interpretability of the programs. Various algorithms have been proposed for learning the parameters of probabilistic logic programs under the distribution semantics, such as ProbLog2 [3] and EMBLEM [1]. Recently, systems for learning the structure of these programs have started to appear. Among these, SLIPCOVER [2] performs a beam search in the space of clauses using the log-likelihood as the heuristics.

This system was able to learn good quality solutions in a variety of domains [2] but is usually costly in terms of time.

In this paper, we propose the system SEMPRES for “Structure Learning by MaPREduce”, that is a MapReduce version of SLIPCOVER.

We experimentally evaluated SEMPRES by running it on various datasets using 1, 8, 16 and 32 nodes. The results show that SEMPRES significantly reduces SLIPCOVER running time, even if the speedup is often less than linear because of a (sometimes) relevant overhead.

The paper is organized as follows. Section 2 summarises PLP under the distribution semantics. Section 3 discusses SEMPRES and presents the experiments, while Section 4 concludes the paper.

2 Probabilistic Logic Programming

We introduce PLP focusing on the distribution semantics. We consider Logic Programs with Annotated Disjunctions (LPADs) as the language for their general syntax and we do not allow function symbols; for the treatment of function symbols see [4].

An LPAD is a finite set of annotated disjunctive clauses of the form $h_{i1} : \Pi_{i1}; \dots; h_{in_i} : \Pi_{in_i} :- b_{i1}, \dots, b_{im_i}$. where b_{i1}, \dots, b_{im_i} are literals forming the *body*, h_{i1}, \dots, h_{in_i} are atoms whose disjunction forms the *head* and $\Pi_{i1}, \dots, \Pi_{in_i}$ are real numbers in the interval $[0, 1]$ s.t. $\sum_{k=1}^{n_i} \Pi_{ik} \leq 1$. If $\sum_{k=1}^{n_i} \Pi_{ik} < 1$, the head contains an extra atom *null* absent from the body of every clause annotated with $1 - \sum_{k=1}^{n_i} \Pi_{ik}$.

Given an LPAD P , the grounding $ground(P)$ is obtained by replacing variables with terms from the Herbrand universe in all possible ways. If P does not contain function symbols and P is finite, $ground(P)$ is finite as well. $ground(P)$ is still an LPAD from which we can obtain a normal logic program by selecting a head atom for each ground clause. In this way we obtain a so-called *world* to which we can assign a probability by multiplying the probabilities of all the head atoms chosen. We thus get a probability distribution over worlds from which we can define a probability distribution over the truth values of a ground atom: the probability of an atom q being true is the sum of the probabilities of the worlds where q is true³.

3 Distributed Structure Learning

SEMPRES parallelizes three operations of the structure learning algorithm SLIPCOVER [2] by employing n workers, one master and $n - 1$ slaves.

The first operation is the scoring of the clause refinements [lines 8-14 in Algorithm 1]: when the revisions for a clause are generated, the master process splits them evenly into n subsets and assigns $n - 1$ subsets to the slaves. One subset is handled by the master. Then, SEMPRES enters the *Map phase* [lines 15-25], when each worker scores a set of refinements by means of (serial) EMBLEM [1] which is run over a theory containing only one clause. Then, SEMPRES enters the *Reduce phase* [lines 26-31], where the master collects all sets of scored refinements from the workers and updates the beam of promising clauses and the sets of target and background

³ We assume that the worlds all have a two-valued well-founded model.

Algorithm 1. Function SEMPRES

```

1: function SEMPRES( $I, n, NInt, NS, NA, NI, NV, \epsilon, \delta$ )
2:    $IBs \leftarrow \text{INITIALBEAMS}(I, NInt, NS, NA)$   $\triangleright$  Clause search
3:    $TC \leftarrow [], BC \leftarrow []$ 
4:   for all ( $PredSpec, Beam$ )  $\in IBs$  do
5:      $Steps \leftarrow 1, NewBeam \leftarrow []$ 
6:     repeat
7:       while  $Beam$  is not empty do
8:         if MASTER then
9:            $Refs \leftarrow \text{CLAUSEREFINEMENTS}((Cl, Literals), NV)$ 
10:          Split evenly  $Refs$  into  $n$  subsets
11:          Send  $Refs_j$  to worker  $j$ 
12:         else  $\triangleright$  the  $j$ -th slave
13:           Receive  $Refs_j$  from master
14:         end if
15:         for all ( $Cl', Literals'$ )  $\in Refs_j$  do
16:           ( $LL', \{Cl''\}$ )  $\leftarrow \text{EMBLEM}(I, \{Cl'\}, \epsilon, \delta)$ 
17:            $NewBeam_j \leftarrow \text{INSERT}((Cl'', Literals'), LL')$ 
18:           if  $Cl''$  is range restricted then
19:             if  $Cl''$  has a target predicate in the head then
20:                $TC \leftarrow \text{INSERT}((Cl'', Literals'), LL')$ 
21:             else
22:                $BC \leftarrow \text{INSERT}((Cl'', Literals'), LL')$ 
23:             end if
24:           end if
25:         end for
26:         if MASTER then
27:           Collect all the sets  $NewBeam_j$  from workers
28:           Update  $NewBeam, TC, BC$ 
29:         else  $\triangleright$  the  $j$ -th slave
30:           Send the set  $NewBeam_j$  to master
31:         end if
32:       end while
33:        $Beam \leftarrow NewBeam, Steps \leftarrow Steps + 1$ 
34:     until  $Steps > NI$ 
35:   end for
36:   if MASTER then
37:      $\mathcal{T} \leftarrow \emptyset, \mathcal{TLL} \leftarrow -\infty$   $\triangleright$  Theory search
38:     repeat
39:       Remove the first couple ( $Cl, LL$ ) from  $TC$ 
40:       ( $LL', \mathcal{T}'$ )  $\leftarrow \text{EMBLEM}^{MR}(I, \mathcal{T} \cup \{Cl\}, n, \epsilon, \delta)$ 
41:       if  $LL' > \mathcal{TLL}$  then
42:          $\mathcal{T} \leftarrow \mathcal{T}', \mathcal{TLL} \leftarrow LL'$ 
43:       end if
44:     until  $TC$  is empty
45:      $\mathcal{T} \leftarrow \mathcal{T} \cup_{(Cl, LL) \in BC} \{Cl\}$ 
46:     ( $LL, \mathcal{T}$ )  $\leftarrow \text{EMBLEM}^{MR}(I, \mathcal{T}, n, \epsilon, \delta)$ 
47:     return  $\mathcal{T}$ 
48:   end if
49: end function

```

clauses (TC and BC respectively): the scored refinements are inserted in order of LL into these lists.

The second parallelized operation is parameter learning for the theories with the target clauses. In this phase [lines 37-44], each clause from TC is tentatively added to the theory, which is initially empty. In the end, it contains all the clauses that improved its LL (search in the space of theories). In this case, parameter learning may be quite expensive since the theory contains multiple clauses, so a MapReduce version of EMBLEM called EMBLEM^{MR} is used.

The third parallelized operation is the final parameter optimization for the theory including also the background clauses [lines 45-46]. All the background clauses are added to the theory previously learned and the parameters of the resulting theory are learned by means of EMBLEM^{MR} .

SEMPRE was implemented in Yap Prolog using the `lam_mpi` library for interfacing Prolog with the Message Passing Interface (MPI) framework.

SEMPRE was tested on the following seven real world datasets: Hepatitis, Mutagenesis, UWCSE, Carcinogenesis, IMDB, HIV and WebKB. All experiments were performed on GNU/Linux machines with an Intel Xeon Haswell E5-2630 v3 (2.40GHz) CPU with 8GB of memory allocated to the job.

Figure 1 shows the speedup of SEMPRES as a function of

the number of workers. The speedup is always larger than 1 and grows with the number of workers, except for HIV and IMDB, where there is a slight decrease for 16 and 32 workers due to the overhead; however, these two datasets were the smallest and less in need of a parallel solution.

Figure 1. SEMPRES speedup.

4 Conclusions

The paper presents the algorithm SEMPRES for learning the structure of probabilistic logic programs under the distribution semantics. SEMPRES is a MapReduce implementation of SLIPCOVER, exploiting modern computing infrastructures for performing learning in parallel. The results show that parallelization is indeed effective at reducing running time, even if in some cases the overhead may be significant.
