We report the first measurement of absolute hadronic branching fractions of $\Lambda_{c}^{+}$baryon at the $\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}$production threshold, in the 30 years since the $\Lambda_{c}^{+}$discovery. In total, twelve Cabibbo-favored $\Lambda_{c}^{+}$hadronic decay modes are analyzed with a double-tag technique, based on a sample of $567 \mathrm{pb}^{-1}$ of $e^{+} e^{-}$collisions at $\sqrt{s}=4.599 \mathrm{GeV}$ recorded with the BESIII detector. A global least-squares

#### Abstract

fitter is utilized to improve the measured precision. Among the measurements for twelve $\Lambda_{c}^{+}$decay modes, the branching fraction for $\Lambda_{c}^{+} \rightarrow p K^{-} \pi^{+}$is determined to be ( $5.84 \pm 0.27 \pm 0.23$ ) \%, where the first uncertainty is statistical and the second is systematic. In addition, the measurements of the branching fractions of the other eleven Cabibbo-favored hadronic decay modes are significantly improved.

PACS numbers: $14.20 . \mathrm{Lq}, 13.30 . \mathrm{Eg}, 13.66 . \mathrm{Bc}$

Charmed baryon decays provide crucial information ${ }_{175}$ for the study of both strong and weak interactions.176 Hadronic decays of $\Lambda_{c}^{+}$, the lightest charmed baryon ${ }_{177}$ with quark configuration $u d c$, provide important input to $\Lambda_{b}$ physics as $\Lambda_{b}$ decays dominantly to $\Lambda_{c}^{+}[1,2]$. Improved measurements of the $\Lambda_{c}^{+}$hadronic decays can $_{178}$ be used to constrain fragmentation functions of charm ${ }_{179}$ and bottom quarks by counting inclusive heavy flavor ${ }_{180}$ baryons [3]. Most $\Lambda_{c}^{+}$branching fractions (BF) have until $1_{81}$ now been obtained by combining measurements of ratios with a single branching fraction of the golden reference mode $\Lambda_{c}^{+} \rightarrow p K^{-} \pi^{+}$, thus introducing strong correlations and compounding uncertainties. The experimentally averaged $\mathrm{BF}, \mathcal{B}\left(\Lambda_{c}^{+} \rightarrow p K^{-} \pi^{+}\right)=(5.0 \pm 1.3) \%[4],{ }_{183}^{182}$ has large uncertainty due to the introduction of mod- ${ }^{183}$ el assumptions on $\Lambda_{c}^{+}$inclusive decays in these mea- ${ }^{184}$ surements [5]. Recently, the Belle experiment reported ${ }^{185}$ $\mathcal{B}\left(\Lambda_{c}^{+} \rightarrow p K^{-} \pi^{+}\right)=\left(6.84 \pm 0.24_{-0.27}^{+0.21}\right) \%$ with a preci- ${ }^{186}$ sion improved by a factor of 5 over previous results [6] ${ }^{187}$ However, most hadronic BFs still have poor precision [4]. ${ }_{188}^{188}$ In this Letter, we present the first simultaneous determi- ${ }^{189}$ nation of multiple $\Lambda_{c}^{+}$absolute BFs.

Our analysis is based on a data sample with an in- ${ }^{191}$ tegrated luminosity of $567 \mathrm{pb}^{-1}$ [7] collected with the ${ }^{192}$ BESIII detector [8] at the center-of-mass energy of $\sqrt{s}=$ 4.599 GeV . At this energy, no additional hadrons accompanying the $\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}$pairs are produced. Previously, the Mark III collaboration measured $D$ hadronic BFs at the ${ }_{193}$ $D \bar{D}$ threshold using a double-tag technique, which relies on fully reconstructing both $D$ and $\bar{D}$ decays [9] ${ }_{195}^{194}$ This technique obviates the need for knowledge of the ${ }_{196}^{195}$ luminosity or the production cross section. We em- ${ }_{197}^{196}$ ploy a similar technique [10] using BESIII data near ${ }^{198}$ the $\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}$threshold, resulting in improved measure- ${ }^{198}$ ments of charge-averaged BFs for twelve Cabibbo-favored ${ }^{190}$ hadronic decay modes: $\Lambda_{c}^{+} \rightarrow p K_{S}^{0}, p K^{-} \pi^{+}, p K_{S}^{0} \pi^{0}{ }^{2001}$ $p K_{S}^{0} \pi^{+} \pi^{-}, p K^{-} \pi^{+} \pi^{0}, \Lambda \pi^{+}, \Lambda \pi^{+} \pi^{0}, \Lambda \pi^{+} \pi^{-} \pi^{+}, \Sigma^{0} \pi^{+}{ }_{202}$ $\Sigma^{+} \pi^{0}, \Sigma^{+} \pi^{+} \pi^{-}$, and $\Sigma^{+} \omega[11]$. Throughout the Letter, ${ }_{203}$ charge-conjugate modes are implicitly assumed, unless ${ }_{204}^{203}$ otherwise stated.

To identify the $\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}$signal candidates, we first recon- ${ }^{205}$ struct one $\bar{\Lambda}_{c}^{-}$baryon [called a single tag (ST)] through ${ }_{207}^{206}$ the final states of any of the twelve modes. For a given ${ }^{208}$ decay mode $j$, the ST yield is determined to be

$$
\begin{equation*}
N_{j}^{\mathrm{ST}}=N_{\Lambda_{c}^{+}{\overline{\Lambda_{c}^{-}}}_{-} \cdot \mathcal{B}_{j} \cdot \varepsilon_{j}, ~}^{\text {, }} \tag{1}
\end{equation*}
$$

where $N_{\Lambda_{c}^{+}} \bar{\Lambda}_{c}^{-}$is the total number of produced $\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}{ }^{212}$ pairs and $\varepsilon_{j}$ is the corresponding efficiency. Then we ${ }_{213}$ define double-tag (DT) events as those where the partner ${ }_{214}$ $\Lambda_{c}^{+}$recoiling against the $\bar{\Lambda}_{c}^{-}$is reconstructed in one of the $2_{215}$
twelve modes. That is, in DT events, the $\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}$event is fully reconstructed. The DT yield with $\Lambda_{c}^{+} \rightarrow i$ (signal mode) and $\bar{\Lambda}_{c}^{-} \rightarrow j$ (tagging mode) is

$$
\begin{equation*}
N_{i j}^{\mathrm{DT}}=N_{\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}} \cdot \mathcal{B}_{i} \cdot \mathcal{B}_{j} \cdot \varepsilon_{i j} \tag{2}
\end{equation*}
$$

where $\varepsilon_{i j}$ is the efficiency for simultaneously reconstructing modes $i$ and $j$. Hence, the ratio of the DT yield ( $\left.N_{i j}^{\mathrm{DT}}\right)$ and ST yield $\left(N_{j}^{\mathrm{ST}}\right)$ provides an absolute measurement of the BF:

$$
\begin{equation*}
\mathcal{B}_{i}=\frac{N_{i j}^{\mathrm{DT}}}{N_{j}^{\mathrm{ST}}} \frac{\varepsilon_{j}}{\varepsilon_{i j}} \tag{3}
\end{equation*}
$$

Because of the large acceptance of the BESIII detector and the low multiplicities of $\Lambda_{c}$ hadronic decays, $\varepsilon_{i j} \approx \varepsilon_{i} \varepsilon_{j}$. Hence, the ratio $\varepsilon_{j} / \varepsilon_{i j}$ is insensitive to most systematic effects associated with the decay mode $j$, and a signal $\mathrm{BF} \mathcal{B}_{i}$ obtained using this procedure is nearly independent of the efficiency of the tagging mode. Therefore, $\mathcal{B}_{i}$ is sensitive to the signal mode efficiency $\left(\varepsilon_{i}\right)$, whose uncertainties dominate the contribution to the systematic error from the efficiencies. According to Eqs. (1) and (2), the total DT yield with $\Lambda_{c}^{+} \rightarrow i$ (signal mode) over the twelve ST modes is determined to be

$$
\begin{equation*}
N_{i-}^{\mathrm{DT}}=N_{\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}} \cdot \sum_{j} \mathcal{B}_{i} \cdot \mathcal{B}_{j} \cdot \varepsilon_{i-}^{\mathrm{DT}}, \tag{4}
\end{equation*}
$$

where $\varepsilon_{i-}^{\mathrm{DT}} \equiv \frac{\sum_{j}\left(\mathcal{B}_{j} \cdot \varepsilon_{i j}\right)}{\sum_{j} \mathcal{B}_{j}}$ is the average DT efficiency weighted over the twelve modes.

The BESIII detector is an approximately cylindrically symmetric detector with $93 \%$ coverage of the solid angle around the $e^{+} e^{-}$interaction point (IP). The components of the apparatus, ordered by distance from the IP, are a 43-layer small-cell main drift chamber (MDC), a time-of-flight (TOF) system based on plastic scintillators with two layers in the barrel region and one layer in the end-cap region, a 6240 -cell $\mathrm{CsI}(\mathrm{Tl})$ crystal electromagnetic calorimeter (EMC), a superconducting solenoid magnet providing a 1.0 T magnetic field aligned with the beam axis, and resistive-plate muon-counter layers interleaved with steel. The momentum resolution for charged tracks in the MDC is $0.5 \%$ for a transverse momentum of $1 \mathrm{GeV} / c$. The energy resolution in the EMC is $2.5 \%$ in the barrel region and $5.0 \%$ in the end-cap region for 1 GeV photons. Particle identification (PID) for charged tracks combines measurements of the energy deposit $\mathrm{d} E / \mathrm{d} x$ in MDC and flight time in TOF and forms likelihoods $\mathcal{L}(h)(h=p, K, \pi)$ for a hadron $h$ hypothesis. More details about the BESIII detector are provided elsewhere [8].

High-statistics Monte Carlo (MC) simulations of $e^{+} e^{-}$ annihilations are used to understand backgrounds and to estimate detection efficiencies. The simulation includes the beam-energy spread and initial-state radiation (ISR) of the $e^{+} e^{-}$collisions as simulated with KKMC [12]. The inclusive MC sample consists of $\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}$events, $D_{(s)}$ production [13], ISR return to lower-mass $\psi$ states, and continuum processes $e^{+} e^{-} \rightarrow q \bar{q}(q=u, d, s)$. Decay modes as specified in the Particle Data Group summary (PDG) [4] are modeled with EVTGEN [14]. For the MC production of $e^{+} e^{-} \rightarrow \Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}$, the observed cross sections are taken into account, and phase-space-generated $\Lambda_{c}^{+}$decays are reweighted according to the observed behaviors in data. All final tracks and photons are fed into a GEANT4-based [15] detector simulation package.

Charged tracks detected in the MDC must satisfy $|\cos \theta|<0.93$ (where $\theta$ is the polar angle with respect to the beam direction) and have a distance of closest approach to the IP of less than 10 cm along the beam axis and less than 1 cm in the perpendicular plane, except for those used for reconstructing $K_{S}^{0}$ and $\Lambda$ decays. Tracks are identified as protons when the PID determines this hypothesis to have the greatest likelihood $(\mathcal{L}(p)>\mathcal{L}(K)$ and $\mathcal{L}(p)>\mathcal{L}(\pi)$ ), while charged kaons and pions are discriminated based on comparing the likelihoods for these two hypotheses $(\mathcal{L}(K)>\mathcal{L}(\pi)$ or $\mathcal{L}(\pi)>\mathcal{L}(K))$.

Showers in the EMC not associated with any charged ${ }_{275}$ track are identified as photon candidates after fulfill-276 ing the following requirements. The deposited ener-277 gy is required to be larger than 25 MeV in the bar-278 rel $(|\cos \theta|<0.8)$ region and 50 MeV in the end-cap ${ }_{279}$ region $(0.84<|\cos \theta|<0.92)$. To suppress electronic ${ }_{280}$ noise and showers unrelated to the event, the EMC time ${ }_{281}$ deviation from the event start time is required to be with ${ }^{-282}$ in $(0,700)$ ns. The $\pi^{0}$ candidates are reconstructed from ${ }_{283}$ photon pairs, and their invariant masses are required $\mathrm{to}_{284}$ satisfy $115<M(\gamma \gamma)<150 \mathrm{MeV} / c^{2}$. To improve momen- ${ }_{285}$ tum resolution, a mass-constrained fit to the $\pi^{0}$ nominal $_{286}$ mass is applied to the photon pairs and the resulting ${ }_{287}$ energy and momentum of the $\pi^{0}$ are used for further ${ }_{288}$ analysis.

289
Candidates for $K_{S}^{0}$ and $\Lambda$ are formed by combining ${ }_{290}$ two oppositely charged tracks into the final states $\pi^{+} \pi^{-}{ }_{291}$ and $p \pi^{-}$. For these two tracks, their distances of clos-292 est approaches to the IP must be within $\pm 20 \mathrm{~cm}$ along ${ }_{293}$ the beam direction. No distance constraints in the trans-294 verse plane are required. The charged $\pi$ is not subject-295 ed to the PID requirements described above, while pro-296 ton PID is implemented in order to improve signal sig-297 nificance. The two daughter tracks are constrained to298 originate from a common decay vertex by requiring the $2_{299}$ $\chi^{2}$ of the vertex fit to be less than 100. Furthermore,300 the decay vertex is required to be separated from the $3_{301}$ IP by a distance of at least twice the fitted vertex res-302 olution. The fitted momenta of the $\pi^{+} \pi^{-}$and $p \pi^{-}$are303 used in the further analysis. We impose requirements304 $487<M\left(\pi^{+} \pi^{-}\right)<511 \mathrm{MeV} / c^{2}$ and $1111<M\left(p \pi^{-}\right)<305$ $1121 \mathrm{MeV} / c^{2}$ to select $K_{S}^{0}$ and $\Lambda$ signal candidates, re-306

FIG. 1. Fits to the ST $M_{\mathrm{BC}}$ distributions in data for the different decay modes. Points with error bars are data, solid lines are the sum of the fit functions, and dashed lines are the background shapes.
spectively, which are within about 3 standard deviations from their nominal masses. To form $\Sigma^{0}, \Sigma^{+}$and $\omega$ candidates, requirements on the invariant masses of $1179<$ $M(\Lambda \gamma)<1203 \mathrm{MeV} / c^{2}, 1176<M\left(p \pi^{0}\right)<1200 \mathrm{MeV} / c^{2}$ and $760<M\left(\pi^{+} \pi^{-} \pi^{0}\right)<800 \mathrm{MeV} / c^{2}$, are imposed.

When we reconstruct the decay modes $p K_{S}^{0} \pi^{0}$, $p K_{S}^{0} \pi^{+} \pi^{-}$and $\Sigma^{+} \pi^{+} \pi^{-}$, possible backgrounds from $\Lambda \rightarrow$ $p \pi^{-}$in the final states are rejected by requiring $M\left(p \pi^{-}\right)$ outside the range $(1110,1120) \mathrm{MeV} / c^{2}$. In addition, for the mode $p K_{S}^{0} \pi^{0}$, candidate events within the range $1170<M\left(p \pi^{0}\right)<1200 \mathrm{MeV} / c^{2}$ are excluded to suppress $\Sigma^{+}$backgrounds. To remove $K_{S}^{0}$ candidates in the modes $\Lambda \pi^{+} \pi^{-} \pi^{+}, \Sigma^{+} \pi^{0}$ and $\Sigma^{+} \pi^{+} \pi^{-}$, masses of any pairs of $\pi^{+} \pi^{-}$and $\pi^{0} \pi^{0}$ are not allowed to fall in the range (480, 520) $\mathrm{MeV} / c^{2}$.

To discriminate $\Lambda_{c}$ candidates from background, two variables reflecting energy and momentum conservation are used. First, we calculate the energy difference, $\Delta E \equiv E-E_{\text {beam }}$, where $E$ is the total measured energy of the $\Lambda_{c}$ candidate and $E_{\text {beam }}$ is the average value of the $e^{+}$and $e^{-}$beam energies. For each tag mode, candidates are rejected if they fail the $\Delta E$ requirements in Table I, which correspond to about 3 times the resolutions. Second, we define the beam-constrained mass $M_{\mathrm{BC}}$ of the $\Lambda_{c}$ candidates by substituting the beamenergy $E_{\text {beam }}$ for the energy $E$ of the $\Lambda_{c}$ candidates, $M_{\mathrm{BC}} c^{2} \equiv \sqrt{E_{\text {beam }}^{2}-p^{2} c^{2}}$, where $p$ is the measured $\Lambda_{c}$ momentum in the center-of-mass system of the $e^{+} e^{-}$collision. Figure 1 shows the $M_{\mathrm{BC}}$ distributions for the ST samples, where evident $\Lambda_{c}$ signals peak at the nominal $\Lambda_{c}$ mass position $(2286.46 \pm 0.14) \mathrm{MeV} / c^{2}$ [4]. The MC simulations show that peaking backgrounds and cross feeds among the twelve ST modes are negligible.

TABLE I. Requirement on $\Delta E$, ST yields, DT yields and detection efficiencies for each of the decay modes. The uncertainties are statistical only. The quoted efficiencies do not include any subleading BFs.

| Mode | $\Delta E(\mathrm{MeV})$ | $N_{j}^{S T}$ | $\varepsilon_{j}(\%)$ | $N_{i-}^{\mathrm{DT}}$ | $\varepsilon_{i-}^{\mathrm{DT}}(\%)$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $p K_{S}^{0}$ | $(-20,20)$ | $1243 \pm 37$ | 55.9 | $97 \pm 10$ | 16.6 |
| $p K^{-} \pi^{+}$ | $(-20,20)$ | $6308 \pm 88$ | 51.2 | $420 \pm 22$ | 14.1 |
| $p K_{S}^{0} \pi^{0}$ | $(-30,20)$ | $558 \pm 33$ | 20.6 | $47 \pm 8$ | 6.8 |
| $p K_{S}^{0} \pi^{+} \pi^{-}$ | $(-20,20)$ | $485 \pm 29$ | 21.4 | $34 \pm 6$ | 6.4 |
| $p K^{-} \pi^{+} \pi^{0}$ | $(-30,20)$ | $1849 \pm 71$ | 19.6 | $176 \pm 14$ | 7.6 |
| $\Lambda \pi^{+}$ | $(-20,20)$ | $706 \pm 27$ | 42.2 | $60 \pm 8$ | 12.7 |
| $\Lambda \pi^{+} \pi^{0}$ | $(-30,20)$ | $1497 \pm 52$ | 15.7 | $101 \pm 13$ | 5.4 |

| $\Sigma^{+} \pi^{0}$ | $(-50,30)$ | $309 \pm 24$ | 23.8 | $25 \pm 5$ | 8.0 |
| $\Sigma^{+} \pi^{+} \pi^{-}$ | $(-30,20)$ | $1156 \pm 49$ | 24.2 | $80 \pm 9$ | 8.1 |
| $\Sigma^{+} \omega$ | $(-30,20)$ | $157 \pm 22$ | 9.9 | $13 \pm 3$ | 3.8 |

We perform unbinned extended maximum likelihood fits to the $M_{\mathrm{BC}}$ distributions to obtain the ST yields, as illustrated in Fig. 1. In each fit, the signal shape is derived from MC simulations of the signal ST modes convolved with a Gaussian function to account for imperfect modeling of the detector resolution and beam-energy spread. The parameters of the Gaussians are allowed to vary in the fits. Backgrounds for each mode are described with the ARGUS function [16]. The resultant ST yields in the signal region $2276<M_{\mathrm{BC}}<2300 \mathrm{MeV} / c^{2}$ and the corresponding detection efficiencies are listed in Table I.

In the signal candidates of the twelve ST modes, a specific mode $\Lambda_{c}^{+} \rightarrow i$ is formed from the remaining tracks and showers recoiling against the $\mathrm{ST} \bar{\Lambda}_{c}^{-}$. We combine the DT signal candidates over the twelve ST modes and plot the distributions of the $M_{\mathrm{BC}}$ variable in Fig. 2. We follow the same fit strategy as in the ST samples to estimate the total DT yield $N_{i-}^{\mathrm{DT}}$ in Eq. (4), except that the DT signal shapes are derived from the DT signal MC samples and convolved with the Gaussian function. The parameters of the Gaussians are also allowed to vary in the fits. The extracted DT yields are listed in Table I. The $12 \times 12$ DT efficiencies $\varepsilon_{i j}$ are evaluated based on ${ }_{344}$ the DT signal MC samples, in order to extract the BFs. ${ }^{345}$

Main sources of systematic uncertainties related to the ${ }^{346}$ measurement of BFs include tracking, PID, reconstruc-347 tion of intermediate states and intermediate BFs. For348 the $\Delta E$ and $M_{\mathrm{BC}}$ requirements, the uncertainties are ${ }^{349}$ negligible, as we correct resolutions in MC samples to350 accord with those in data. Uncertainties associated with351 the efficiencies of the tracking and PID of charged par-352 ticles are estimated by studying a set of control sam-353 ples of $e^{+} e^{-} \rightarrow \pi^{+} \pi^{+} \pi^{-} \pi^{-}, K^{+} K^{-} \pi^{+} \pi^{-}$and $p \bar{p} \pi^{+} \pi^{-}{ }_{354}$ based on data taken at energies above $\sqrt{s}=4.0 \mathrm{GeV} .355$ An uncertainty of $1.0 \%$ is assigned to each $\pi^{0}$ due to the ${ }_{356}$ reconstruction efficiency. The uncertainties of detecting ${ }_{357}$ $K_{S}^{0}$ and $\Lambda$ are determined to be $1.2 \%$ and $2.5 \%$, respec-358

FIG. 2. Fits to the DT $M_{\mathrm{BC}}$ distributions in data for different signal modes. Points with error bars are data, solid lines are the sum of fit functions, and dashed lines are background shapes.

TABLE II. Summary of systematic uncertainties, in percent. The total numbers are derived from the least-squares fit, by taking into account correlations among different modes.

| Source | Tracking PID $K_{S}^{0}$ |  | $\Lambda$ | $\pi^{0}$ | Signal MC <br> model |  |  |  |  |  |  |  | Quoted <br> stat. | BFs | Total |

tively. Reweighting factors for the twelve signal models are varied within their statistical uncertainties obtained from the ST data samples. Deviations of the resultant efficiencies are taken into account in systematic uncertainties. Systematic uncertainties due to limited statistics in MC samples are included. Uncertainties on the BFs of intermediate state decays from the PDG [4] are also included. A summary of systematic uncertainties are given in Table II.

We use a least-squares fitter, which considers statistical and systematic correlations among the different hadronic modes, to obtain the BFs of the twelve $\Lambda_{c}^{+}$decay modes globally. Details of this fitter are discussed in Ref. [17]. In the fitter, the precisions of the twelve BFs are constrained to a common variable, $N_{\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}}$, according to Eqs. (1) and

TABLE III. Comparison of the measured BFs in this work ${ }_{38}^{379}$ with previous results from PDG [4]. For our results, the first ${ }^{380}$ uncertainties are statistical and the second are systematic.

| Mode | This work (\%) | PDG (\%) |
| :--- | :---: | :---: |
| $p K_{S}^{0}$ | $1.52 \pm 0.08 \pm 0.03$ | $1.15 \pm 0.30$ |
| $p K^{-} \pi^{+}$ | $5.84 \pm 0.27 \pm 0.23$ | $5.0 \pm 1.3$ |
| $p K_{S}^{0} \pi^{0}$ | $1.87 \pm 0.13 \pm 0.05$ | $1.65 \pm 0.50$ |
| $p K_{S}^{0} \pi^{+} \pi^{-}$ | $1.53 \pm 0.11 \pm 0.09$ | $1.30 \pm 0.35$ |
| $p K^{-} \pi^{+} \pi^{0}$ | $4.53 \pm 0.23 \pm 0.30$ | $3.4 \pm 1.0$ |
| $\Lambda \pi^{+}$ | $1.24 \pm 0.07 \pm 0.03$ | $1.07 \pm 0.28$ |
| $\Lambda \pi^{+} \pi^{0}$ | $7.01 \pm 0.37 \pm 0.19$ | $3.6 \pm 1.3$ |
| $\Lambda \pi^{+} \pi^{-} \pi^{+}$ | $3.81 \pm 0.24 \pm 0.18$ | $2.6 \pm 0.7$ |
| $\Sigma^{0} \pi^{+}$ | $1.27 \pm 0.08 \pm 0.03$ | $1.05 \pm 0.28$ |

| $\Sigma^{+} \pi^{+} \pi^{-}$ | $4.25 \pm 0.24 \pm 0.20$ | $3.6 \pm 1.0$ |
| $\Sigma^{+} \omega$ | $1.56 \pm 0.20 \pm 0.07$ | $2.7 \pm 1.0$ |

(4). In total, there are thirteen free parameters (twelve $\mathcal{B}_{i_{397}}{ }^{396}$ and $N_{\Lambda_{c}^{+}}{\overline{\Lambda_{c}^{-}}}_{c}$ ) to be estimated. As peaking backgrounds $\mathrm{in}_{398}$ ST modes and cross feeds among the twelve ST modes are $_{399}$ suppressed to a negligible level, they are not considered ${ }_{400}$ in the fit. 401
The extracted BFs of $\Lambda_{c}^{+}$are listed in Table $\mathrm{III}_{402}$ the correlation matrix is available in the Supplemental ${ }_{403}$ Material [18]. The total number of $\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}$pairs produced ${ }_{404}$ is obtained to be $N_{\Lambda_{c}^{+}}{\overline{\Lambda_{c}^{-}}}^{=}(105.9 \pm 4.8 \pm 0.5) \times 10^{3}$. The ${ }_{405}$ goodness-of-fit is evaluated as $\chi^{2} / \mathrm{ndf}=9.9 /(24-13)={ }_{406}$ 0.9 .

To summarize, twelve Cabibbo-favored $\Lambda_{c}^{+}$decay rates408 are measured by employing a double-tag technique, based409 on a sample of threshold data at $\sqrt{s}=4.599 \mathrm{GeV}$ col-410 lected at BESIII. This is the first absolute measurement ${ }_{411}$ of the $\Lambda_{c}^{+}$decay branching fractions at the $\Lambda_{c}^{+} \bar{\Lambda}_{c}^{-}$pro-412 duction threshold, in the 30 years since the $\Lambda_{c}^{+}$discov-413 ery. A comparison with previous results is presented in414 Table III. For the golden mode $\mathcal{B}\left(p K^{-} \pi^{+}\right)$, our result is415 consistent with that in PDG, but lower than Belle's with416
a significance of about $2 \sigma$. For the branching fractions of the other modes, the precisions are improved by factors of $3 \sim 6$ compared to the world average values.

The BESIII collaboration thanks the staff of BEPCII and the IHEP computing center for their strong support.
